

Automated Security Log Monitoring Lab

Objective

The purpose of this lab was to create an automated system for monitoring security events using PowerShell. The goal was to collect recent security logs, filter for errors and failed activities, and automate the process using Task Scheduler.

Script Creation

A PowerShell script was created to collect recent Security Event Log entries. The script filters for Error and FailureAudit events and saves the results to a timestamped log file in a designated folder.

This allows for quick identification of potential security issues such as failed login attempts or system errors.

Log Output Verification

The script was executed manually to verify functionality. After running the script, a log file was successfully generated in the output directory.

The log file contains filtered security events with timestamps, confirming that the script is working as intended.

Task Scheduling

To automate the process, a scheduled task was created using Windows Task Scheduler. The task was configured to run the PowerShell script daily at a specified time.

This ensures that security logs are collected automatically without manual intervention.

Conclusion

In this lab, a PowerShell script was successfully created and automated to monitor security logs. This demonstrates how scripting and scheduling can be used to automate repetitive security tasks and improve system monitoring efficiency.
